Date:23/02/2026

1.Introduction:

In today's highly connected digital world, technology plays a central role in almost every aspect of our daily activities, and as a result, we continuously interact with different types of data through mobile phones, websites, sensors, smart devices, and various online platforms. From the moment we wake up and check notifications on our smartphones to the time we go to sleep after browsing social media or watching online videos, we are constantly generating, sharing, receiving, and processing digital information. Every simple action such as sending a text message, making an online payment, scanning a fingerprint to unlock a phone, ordering food through an app, attending online classes, using GPS navigation, or streaming music contributes to the creation and storage of data in digital systems.

This continuous interaction with digital systems forms what can be described as a Daily Data Inventory, which refers to identifying, tracking, and understanding the different types and sources of data that we interact with regularly. Maintaining awareness about our daily data usage helps us understand how digital systems function and how information is categorized, stored, and analyzed.

2. Data from Mobile Applications

Mobile applications are one of the primary sources of digital data in my daily life. I use different apps for communication, payments, shopping, learning, and entertainment. Each app generates different types of data depending on the purpose of usage.

2.1 Payment Applications:

When I use payment apps like Google Pay or PhonePe to transfer money or check my account balance, the system generates structured data.

The transaction details such as transaction ID, date, time, receiver name, and amount are stored in a predefined tabular format inside banking databases. This data follows a strict structure and is easy to search and retrieve. Therefore, payment transaction records are classified as Structured Data.

2.2 Messaging Applications:

When I use WhatsApp to send messages, share images, or send voice notes, different types of data are generated.

• The message metadata (sender name, timestamp, message status) is semi-structured.

• The text message itself is unstructured.

• Images and voice notes are unstructured data.

Since the app contains both structured elements (like timestamps) and flexible content (like free text), messaging apps mainly generate Semi-Structured and Unstructured Data.

2.3 Social Media Applications:

When I use Instagram to upload posts or stories, the system records structured details such as username, upload time, and number of likes. However, the captions, photos, and videos are not stored in tabular format.

Thus:

• Post metadata → Semi-Structured Data

• Images and videos → Unstructured Data

3. Data from Websites:

Websites are another major source of daily data interaction. I browse websites for shopping, education, entertainment, and information.

3.1 E-Commerce Websites:

When I purchase products from Amazon, the system stores my order details such as product name, price, order ID, and delivery address in a structured database.

This information follows a fixed format and is stored in rows and columns. Therefore, order details are classified as Structured Data.

However, product reviews written by customers are free-form text and are considered Unstructured Data.

3.2 Educational Websites:

When I log into college portals or learning platforms, my student ID, attendance records, and marks are stored in structured form.

But lecture videos and uploaded PDF notes are unstructured data because they do not follow a fixed database format.

3.3 Search Engines:

When I search something on Google, my search query is stored along with metadata such as time and location.

• Search history → Structured Data

• Search query text → Semi-Structured Data

4. Data from Sensors:

Sensors play an important role in generating data automatically without manual input.

4.1 Fingerprint Sensor:

When I unlock my phone using fingerprint authentication, the system captures biometric data. This fingerprint information is stored in a structured digital format for verification. Therefore, it is classified as Structured Data.

4.2 GPS Sensor:

When I use location services or navigation apps, the GPS sensor collects coordinates such as latitude and longitude. These coordinates are stored in numeric format inside databases. Hence, GPS location data is Structured Data.

4.3 GPS Sensor:

When I take photos or record videos using my mobile camera, the output is an image or video file. These files contain pixel data and multimedia content, which do not follow rows and columns. Therefore, camera output is classified as Unstructured Data.

4.4 Microphone Sensor

When I give voice commands to Google Assistant, the microphone captures audio signals. These audio files are stored as sound waves and are not structured in tabular format. Hence, they are considered Unstructured Data.

5. Explanation of Data Types:

Structured Data:

Structured data is highly organized information stored in tables with rows and columns. It follows a fixed schema and is easy to manage, search, and analyze. Examples include banking transactions, attendance records, and order details.

Example:

- **Bank Transaction Records:**

When I use Google Pay, the transaction details such as transaction ID, date, time, and amount are stored in a table format. Since each field has a fixed position, it is structured data.

- **Student Attendance Record:**

In a college portal, attendance is stored with fields like Student ID, Name, Date, and Status (Present/Absent). This follows a fixed tabular structure.

- **Employee Salary Database:**

Employee ID, Name, Department, and Salary are stored in rows and columns inside a company database.

Semi-Structured Data:

Semi-structured data does not follow a strict table format but contains tags, metadata, or labels that provide partial organization. Examples include emails, chat messages, and social media posts.

Example:

- **Emails:**

In Gmail, emails contain structured parts like sender, receiver, subject, and date, but the email body is flexible text. Therefore, it is semi-structured.

- **WhatsApp Messages:**

In WhatsApp, each message includes metadata such as timestamp and sender name, but the message content itself is free text.

- **Social Media Posts:**

In Instagram, posts contain username, hashtags, and time (structured elements), but captions and images vary in format.

- **JSON or XML Files:**

These files use tags to organize data but are not stored in strict table format.

Unstructured Data:

Unstructured data does not have a predefined format and includes multimedia content such as images, videos, audio files, and free-form text. It requires advanced processing techniques for analysis.

Example:

- **Photos:**

Images taken using a mobile camera are stored as image files containing pixel data, not in rows and columns.

- **Videos:**

Videos watched on YouTube are multimedia files without tabular structure.

- **Audio Recordings:**

Voice commands given to Google Assistant are stored as sound wave files.

- **PDF Documents**:

Notes, scanned documents, and lecture materials are free-form and not structured in database tables.

6. Conclusion:

In conclusion, my daily interaction with mobile applications, websites, and sensors generates various forms of data that can be classified into structured, semi-structured, and unstructured categories. Payment systems and academic portals mainly generate structured data because they require accuracy and organization. Messaging apps and social media platforms generate semi-structured data due to the presence of metadata combined with flexible content. Sensors such as cameras and microphones generate unstructured data in the form of images, videos, and audio files.

Understanding my daily data inventory helps me recognize how digital systems function and how different types of data are stored and processed. This knowledge is essential for understanding database systems, big data technologies, and modern information systems.
